**APPARATUS COMPRISING EXPANDABLE BISTABLE TUBULARS AND
METHODS FOR THEIR USE IN WELLBORES**

5 **CROSS REFERENCE TO RELATED APPLICATIONS**

This is a divisional of U.S. Serial No. 10/035,994, filed
December 26, 2001, which claims the benefit under 35 U.S.C.
§119(e) to U.S. Provisional Application Serial No. 60/263,934
filed January 24, 2001.

10 **FIELD OF THE INVENTION**

This invention relates to equipment that can be used in the
drilling and completion of wellbores in an underground formation
and in the production of fluids from such wells; and
15 particularly to connection systems for connecting a variety of
tubulars used in wellbores.

BACKGROUND OF THE INVENTION

Fluids such as oil, natural gas and water are obtained from
20 a subterranean geologic formation (a "reservoir") by drilling a
well that penetrates the fluid-bearing formation. Once the well
has been drilled to a certain depth the borehole wall must be
supported to prevent collapse. Conventional well drilling

methods involve the installation of a casing string and cementing between the casing and the borehole to provide support for the borehole structure.

5 Within the casing or within the open wellbore, a variety of tubular components are utilized in, for example, preparation and servicing of the well and for the production of wellbore fluids. In some applications, the use of expandable tubulars is becoming more desirable. In such applications, a tubular component is
10 moved downhole and then expanded at a desired location within the wellbore. With these types of tubulars in particular, the connection of one tubular to another becomes difficult. Connectors or connection systems designed for conventional tubulars do not readily adapt to tubular members that are
15 expanded.

The present invention is directed to overcoming, or at least reducing the effects of one or more of the problems set forth above, and can be useful in other applications as well.

20

SUMMARY OF THE INVENTION

According to one aspect of the present invention, a technique is provided for connecting tubulars, such as those

used within a wellbore. The technique is particularly amenable to use with expandable tubulars. The technique allows such expandable tubulars to be connected and yet expanded as desired. Certain connectors utilized with this technique are particularly helpful in connecting tubulars formed of bistable cells that facilitate expansion of the tubular from a contracted stable state to an expanded stable state.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will hereafter be described with reference to the accompanying drawings, wherein like reference numerals denote like elements, and:

Figures 1A and 1B are illustrations of the forces imposed to make a bistable structure;

Figure 2A and 2B show force-deflection curves of two bistable structures;

Figures 3A - 3F illustrate expanded and collapsed states of three bistable cells with various thickness ratios;

Figures 4A and 4B illustrate a bistable expandable tubular
in its expanded and collapsed states;

Figures 4C and 4D illustrate a bistable expandable tubular
5 in collapsed and expanded states within a wellbore;

Figures 5A and 5B illustrate an expandable packer type of
deployment device;

10 Figures 6A and 6B illustrate a mechanical packer type of
deployment device;

Figures 7A - 7D illustrate an expandable swage type of
deployment device;

15

Figures 8A - 8D illustrate a piston type of deployment
device;

Figures 9A and 9B illustrate a plug type of deployment
20 device;

Figures 10A and 10B illustrate a ball type of deployment
device;

Figure 11 is a schematic of a wellbore utilizing an expandable bistable tubular;

5 Figure 12 illustrates a motor driven radial roller deployment device;

Figure 13 illustrates a hydraulically driven radial roller deployment device;

10

Figure 14 is a partial side elevational view of an alternative embodiment of the present invention;

Figure 15 is a partial side elevational view of an
15 alternative embodiment of the present invention;

Figures 16A-E are partial elevational views of an alternative embodiment of the present invention;

Figures 17A-D are partial perspective views of an
alternative embodiment of the present invention;

Figure 18 is a side elevational view of an expandable
5 slotted tubing having end extensions of the present invention;

Figure 19 is a partial cross-sectional end view of an
embodiment of the connector of the present invention;

10 Figure 20 is a partial cross-sectional side view of an
embodiment of the connector of the present invention;

Figures 21A-21E illustrate the sequential coupling of
adjacent tubulars with a sand barrier;

15

Figure 22 is a cross-sectional view taken generally along
the axis of the connected tubulars illustrated in Figure 21C;

Figures 23A-23C illustrate an alternate embodiment of the
20 connection system illustrated in Figures 21A-21C;

Figures 24A-24C illustrate another alternate embodiment of the connection system illustrated in Figures 21A-21C;

5 Figure 25 is a side view of a crossover device according to one embodiment of the present invention;

Figure 26 is a front view of an alternate embodiment of the crossover device illustrated in Figure 25; and

10 Figures 27A-27D illustrate another alternate embodiment of an exemplary connection system.

While the invention is susceptible to various modifications
15 and alternative forms, specific embodiments thereof have been shown by way of example in the drawings and are herein described in detail. It should be understood, however, that the description herein of specific embodiments is not intended to limit the invention to the particular forms disclosed, but on
20 the contrary, the intention is to cover all modifications,

equivalents, and alternatives falling within the spirit and scope of the invention as defined by the appended claims.

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

Bistable devices used in the present invention can take
5 advantage of a principle illustrated in Figures 1A and 1B.
Figure 1A shows a rod 10 fixed at each end to rigid supports 12.
If the rod 10 is subjected to an axial force it begins to deform
as shown in Figure 1B. As the axial force is increased rod 10
ultimately reaches its Euler buckling limit and deflects to one
10 of the two stable positions shown as 14 and 15. If the buckled
rod is now clamped in the buckled position, a force at right
angles to the long axis can cause the rod to move to either of
the stable positions but to no other position. When the rod is
subjected to a lateral force it must move through an angle β
15 before deflecting to its new stable position.

Bistable systems are characterized by a force deflection
curve such as those shown in Figures 2A and 2B. The externally
applied force 16 causes the rod 10 of Fig. 1B to move in the
20 direction X and reaches a maximum 18 at the onset of shifting
from one stable configuration to the other. Further deflection
requires less force because the system now has a negative spring
rate and when the force becomes zero the deflection to the

second stable position is spontaneous.

The force deflection curve for this example is symmetrical and is illustrated in Figure 2A. By introducing either a
5 precurvature to the rod or an asymmetric cross section the force deflection curve can be made asymmetric as shown in Figure 2B. In this system the force 19 required to cause the rod to assume one stable position is greater than the force 20 required to cause the reverse deflection. The force 20 must be greater than
10 zero for the system to have bistable characteristics.

Bistable structures, sometimes referred to as toggle devices, have been used in industry for such devices as flexible discs, over center clamps, hold-down devices and quick release
15 systems for tension cables (such as in sailboat rigging backstays).

Instead of using the rigid supports as shown in Figures 1A and 1B, a cell can be constructed where the restraint is
20 provided by curved struts connected at each end as shown in Figures 3A - 3F. If both struts 21 and 22 have the same thickness as shown in Figures 3A and 3B, the force deflection curve is linear and the cell lengthens when compressed from its

open position Figure 3B to its closed position Figure 3A. If the cell struts have different thicknesses, as shown in Figures 3C - 3F, the cell has the force deflection characteristics shown in Figure 2B, and does not change in length when it moves
5 between its two stable positions. An expandable bistable tubular can thus be designed so that as the radial dimension expands, the axial length remains constant. In one example, if the thickness ratio is over approximately 2:1, the heavier strut resists longitudinal changes. By changing the ratio of thick-
10 to-thin strut dimensions, the opening and closing forces can be changed. For example, Figures 3C and 3D illustrated a thickness ratio of approximately 3:1, and Figures 3E and 3F illustrate a thickness ratio of approximately 6:1.

15 An expandable bore bistable tubular, such as casing, a tube, a patch, or pipe, can be constructed with a series of circumferential bistable connected cells 23 as shown in Figures 4A and 4B, where each thin strut 21 is connected to a thick strut 22. The longitudinal flexibility of such a tubular can be
20 modified by changing the length of the cells and by connecting each row of cells with a compliant link. Further, the force deflection characteristics and the longitudinal flexibility can also be altered by the design of the cell shape. Figure 4A

illustrates an expandable bistable tubular 24 in its expanded configuration while Figure 4B illustrates the expandable bistable tubular 24 in its contracted or collapsed configuration. Within this application the term "collapsed" is used to identify the configuration of the bistable element or device in the stable state with the smallest diameter, it is not meant to imply that the element or device is damaged in any way. In the collapsed state, bistable tubular 24 is readily introduced into a wellbore 29, as illustrated in Figure 4C.

Upon placement of the bistable tubular 24 at a desired wellbore location, it is expanded, as illustrated in Figure 4D.

The geometry of the bistable cells is such that the tubular cross-section can be expanded in the radial direction to increase the overall diameter of the tubular. As the tubular expands radially, the bistable cells deform elastically until a specific geometry is reached. At this point the bistable cells move, e.g. snap, to a final expanded geometry. With some materials and/or bistable cell designs, enough energy can be released in the elastic deformation of the cell (as each bistable cell snaps past the specific geometry) that the expanding cells are able to initiate the expansion of adjoining bistable cells past the critical bistable cell geometry.

Depending on the deflection curves, a portion or even an entire length of bistable expandable tubular can be expanded from a single point.

5 In like manner if radial compressive forces are exerted on an expanded bistable tubular, it contracts radially and the bistable cells deform elastically until a critical geometry is reached. At this point the bistable cells snap to a final collapsed structure. In this way the expansion of the bistable
10 tubular is reversible and repeatable. Therefore the bistable tubular can be a reusable tool that is selectively changed between the expanded state as shown in Figure 4A and the collapsed state as shown in Figure 4B.

15 In the collapsed state, as in Figure 4B, the bistable expandable tubular is easily inserted into the wellbore and placed into position. A deployment device is then used to change the configuration from the collapsed state to the
expanded state.

20

In the expanded state, as in Figure 4A, design control of the elastic material properties of each bistable cell can be such that a constant radial force can be applied by the tubular

wall to the constraining wellbore surface. The material properties and the geometric shape of the bistable cells can be designed to give certain desired results.

5 One example of designing for certain desired results is an expandable bistable tubular string with more than one diameter throughout the length of the string. This can be useful in boreholes with varying diameters, whether designed that way or as a result of unplanned occurrences such as formation washouts
10 or keyseats within the borehole. This also can be beneficial when it is desired to have a portion of the bistable expandable device located inside a cased section of the well while another portion is located in an uncased section of the well. Figure 11 illustrates one example of this condition. A wellbore 40 is
15 drilled from the surface 42 and comprises a cased section 44 and an openhole section 46. An expandable bistable device 48 having segments 50, 52 with various diameters is placed in the well. The segment with a larger diameter 50 is used to stabilize the openhole section 46 of the well, while the segment having a
20 reduced diameter 52 is located inside the cased section 44 of the well.

Bistable collars or connectors 24A (see Figure 4C) can be designed to allow sections of the bistable expandable tubular to be joined together into a string of useful lengths using the same principle as illustrated in Figure 4A and 4B. This
5 bistable connector 24A also incorporates a bistable cell design that allows it to expand radially using the same mechanism as for the bistable expandable tubular component. Exemplary bistable connectors have a diameter slightly larger than the expandable tubular sections that are being joined. The bistable
10 connector is then placed over the ends of the two sections and mechanically attached to the expandable tubular sections. Mechanical fasteners such as screws, rivets or bands can be used to connect the connector to the tubular sections. The bistable connector typically is designed to have an expansion rate that
15 is compatible with the expandable tubular sections, so that it continues to connect the two sections after the expansion of the two segments and the connector.

Alternatively, the bistable connector can have a diameter
20 smaller than the two expandable tubular sections joined. Then, the connector is inserted inside of the ends of the tubulars and mechanically fastened as discussed above. Another embodiment would involve the machining of the ends of the tubular sections

on either their inner or outer surfaces to form an annular recess in which the connector is located. A connector designed to fit into the recess is placed in the recess. The connector would then be mechanically attached to the ends as described
5 above. In this way the connector forms a relatively flush-type connection with the tubular sections.

A conveyance device 31 transports the bistable expandable tubular lengths and bistable connectors into the wellbore and to
10 the correct position. (See Figures 4C and 4D). The conveyance device may utilize one or more mechanisms such as wireline cable, coiled tubing, coiled tubing with wireline conductor, drill pipe, tubing or casing.

15 A deployment device 33 can be incorporated into the overall assembly to expand the bistable expandable tubular and connectors. (See Figures 4C and 4D). Deployment devices can be of numerous types such as an inflatable packer element, a mechanical packer element, an expandable swage, a piston
20 apparatus, a mechanical actuator, an electrical solenoid, a plug type apparatus, e.g. a conically shaped device pulled or pushed through the tubing, a ball type apparatus or a rotary type expander as further discussed below.

An inflatable packer element is shown in Figures 5A and 5B and is a device with an inflatable bladder, element, or bellows incorporated into the bistable expandable tubular system bottom hole assembly. In the illustration of Figure 5A, the inflatable packer element 25 is located inside the entire length, or a portion, of the initial collapsed state bistable tubular 24 and any bistable expandable connectors (not shown). Once the bistable expandable tubular system is at the correct deployment depth, the inflatable packer element 25 is expanded radially by pumping fluid into the device as shown in Figure 5B. The inflation fluid can be pumped from the surface through tubing or drill pipe, a mechanical pump, or via a downhole electrical pump which is powered via wireline cable. As the inflatable packer element 25 expands, it forces the bistable expandable tubular 24 to also expand radially. At a certain expansion diameter, the inflatable packer element causes the bistable cells in the tubular to reach a critical geometry where the bistable "snap" effect is initiated, and the bistable expandable tubular system expands to its final diameter. Finally the inflatable packer element 25 is deflated and removed from the deployed bistable expandable tubular 24.

A mechanical packer element is shown in Figures 6A and 6B and is a device with a deformable plastic element 26 that expands radially when compressed in the axial direction. The force to compress the element can be provided through a
5 compression mechanism 27, such as a screw mechanism, cam, or a hydraulic piston. The mechanical packer element deploys the bistable expandable tubulars and connectors in the same way as the inflatable packer element. The deformable plastic element 26 applies an outward radial force to the inner circumference of
10 the bistable expandable tubulars and connectors, allowing them in turn to expand from a contracted position (see Figure 6A) to a final deployment diameter (see Figure 6B).

An expandable swage is shown in Figures 7A - 7D and
15 comprises a series of fingers 28 that are arranged radially around a conical mandrel 30. Figures 7A and 7C show side and top views respectively. When the mandrel 30 is pushed or pulled through the fingers 28 they expand radially outwards, as illustrated in Figures 7B and 7D. An expandable swage is used
20 in the same manner as a mechanical packer element to deploy a bistable expandable tubular and connector.

A piston type apparatus is shown in Figures 8A - 8D and

comprises a series of pistons 32 facing radially outwardly and used as a mechanism to expand the bistable expandable tubulars and connectors. When energized, the pistons 32 apply a radially directed force to deploy the bistable expandable tubular assembly as per the inflatable packer element. Figures 8A and 8C illustrate the pistons retracted while Figures 8B and 8D show the pistons extended. The piston type apparatus can be actuated hydraulically, mechanically or electrically.

A plug type actuator is illustrated in Figures 9A and 9B and comprises a plug 34 that is pushed or pulled through the bistable expandable tubulars 24 or connectors as shown in Figure 9A. The plug is sized to expand the bistable cells past their critical point where they will snap to a final expanded diameter as shown in Figure 9B.

A ball type actuator is shown in Figures 10A and 10B and operates when an oversized ball 36 is pumped through the middle of the bistable expandable tubulars 24 and connectors. To prevent fluid losses through the cell slots, an expandable elastomer based liner 38 is run inside the bistable expandable tubular system. The liner 38 acts as a seal and allows the ball 36 to be hydraulically pumped through the bistable tubular 24

and connectors. The effect of pumping the ball 36 through the bistable expandable tubulars 24 and connectors is to expand the cell geometry beyond the critical bistable point, allowing full expansion to take place as shown in Figure 10B. Once the
5 bistable expandable tubulars and connectors are expanded, the elastomer sleeve 38 and ball 36 are withdrawn.

Radial roller type actuators also can be used to expand the bistable tubular sections. Figure 12 illustrates a motor driven
10 expandable radial roller tool. The tool comprises one or more sets of arms 58 that are expanded to a set diameter by means of a mechanism and pivot. On the end of each set of arms is a roller 60. Centralizers 62 can be attached to the tool to locate it correctly inside the wellbore and the bistable tubular
15 24. A motor 64 provides the force to rotate the whole assembly, thus turning the roller(s) circumferentially inside the wellbore. The axis of the roller(s) is such as to allow the roller(s) to rotate freely when brought into contact with the inner surface of the tubular. Each roller can be conically-
20 shaped in section to increase the contact area of roller surface to the inner wall of the tubular. The rollers are initially retracted and the tool is run inside the collapsed bistable tubular. The tool is then rotated by the motor 64, and rollers

60 are moved outwardly to contact the inner surface of the bistable tubular. Once in contact with the tubular, the rollers are pivoted outwardly a greater distance to apply an outwardly radial force to the bistable tubular. The outward movement of
5 the rollers can be accomplished via centrifugal force or an appropriate actuator mechanism coupled between the motor 64 and the rollers 60.

The final pivot position is adjusted to a point where the
10 bistable tubular can be expanded to the final diameter. The tool is then longitudinally moved through the collapsed bistable tubular, while the motor continues to rotate the pivot arms and rollers. The rollers follow a shallow helical path 66 inside the bistable tubular, expanding the bistable cells in their
15 path. Once the bistable tubular is deployed, the tool rotation is stopped and the roller retracted. The tool is then withdrawn from the bistable tubular by a conveyance device 68 that also can be used to insert the tool.

20 Figure 13 illustrates a hydraulically driven radial roller deployment device. The tool comprises one or more rollers 60 that are brought into contact with the inner surface of the bistable tubular by means of a hydraulic piston 70. The outward

radial force applied by the rollers can be increased to a point where the bistable tubular expands to its final diameter.

Centralizers 62 can be attached to the tool to locate it correctly inside the wellbore and bistable tubular 24. The

5 rollers 60 are initially retracted and the tool is run into the collapsed bistable tubular 24. The rollers 60 are then deployed and push against the inside wall of the bistable tubular 24 to expand a portion of the tubular to its final diameter. The entire tool is then pushed or pulled longitudinally through the
10 bistable tubular 24 expanding the entire length of bistable cells 23. Once the bistable tubular 24 is deployed in its expanded state, the rollers 60 are retracted and the tool is withdrawn from the wellbore by the conveyance device 68 used to insert it. By altering the axis of the rollers 60, the tool can
15 be rotated via a motor as it travels longitudinally through the bistable tubular 24.

Power to operate the deployment device can be drawn from one or a combination of sources such as: electrical power
20 supplied either from the surface or stored in a battery arrangement along with the deployment device, hydraulic power provided by surface or downhole pumps, turbines or a fluid accumulator, and mechanical power supplied through an

appropriate linkage actuated by movement applied at the surface or stored downhole such as in a spring mechanism.

The bistable expandable tubular system is designed so the
5 internal diameter of the deployed tubular is expanded to maintain a maximum cross-sectional area along the expandable tubular. This feature enables mono-bore wells to be constructed and facilitates elimination of problems associated with traditional wellbore casing systems where the casing outside
10 diameter must be stepped down many times, restricting access, in long wellbores.

The bistable expandable tubular system can be applied in numerous applications such as an expandable open hole liner
15 where the bistable expandable tubular 24 is used to support an open hole formation by exerting an external radial force on the wellbore surface. As bistable tubular 24 is radially expanded, the tubular moves into contact with the surface forming wellbore
29. These radial forces help stabilize the formations and allow
20 the drilling of wells with fewer conventional casing strings. The open hole liner also can comprise a material, e.g. a wrapping, that reduces the rate of fluid loss from the wellbore into the formations. The wrapping can be made from a variety of

materials including expandable metallic and/or elastomeric materials. By reducing fluid loss into the formations, the expense of drilling fluids can be reduced and the risk of losing circulation and/or borehole collapse can be minimized.

5

Liners also can be used within wellbore tubulars for purposes such as corrosion protection. One example of a corrosive environment is the environment that results when carbon dioxide is used to enhance oil recovery from a producing formation. Carbon dioxide (CO_2) readily reacts with any water (H_2O) that is present to form carbonic acid (H_2CO_3). Other acids can also be generated, especially if sulfur compounds are present. Tubulars used to inject the carbon dioxide as well as those used in producing wells are subject to greatly elevated corrosion rates. The present invention can be used to place protective liners, e.g. a bistable tubular 24, within an existing tubular to minimize the corrosive effects and to extend the useful life of the wellbore tubulars.

20 Another exemplary application involves use of the bistable tubular 24 as an expandable perforated liner. The open bistable cells in the bistable expandable tubular allow unrestricted flow

from the formation while providing a structure to stabilize the borehole.

Still another application of the bistable tubular 24 is as
5 an expandable sand screen where the bistable cells are sized to act as a sand control screen. Also, a filter material can be combined with the bistable tubular as explained below. For example, an expandable screen element can be affixed to the bistable expandable tubular. The expandable screen element can
10 be formed as a wrapping around bistable tubular 24. It has been found that the imposition of hoop stress forces onto the wall of a borehole will in itself help stabilize the formation and reduce or eliminate the influx of sand from the producing zones, even if no additional screen element is used.

15

The above described bistable expandable tubulars can be made in a variety of manners such as: cutting appropriately shaped paths through the wall of a tubular pipe thereby creating an expandable bistable device in its collapsed state; cutting
20 patterns into a tubular pipe thereby creating an expandable bistable device in its expanded state and then compressing the device into its collapsed state; cutting appropriate paths through a sheet of material, rolling the material into a tubular

shape and joining the ends to form an expandable bistable device in its collapsed state; or cutting patterns into a sheet of material, rolling the material into a tubular shape, joining the adjoining ends to form an expandable bistable device in its expanded state and then compressing the device into its collapsed state.

The materials of construction for the bistable expandable tubulars can include those typically used within the oil and gas industry such as carbon steel. They can also be made of specialty alloys (such as a monel, inconel, hastelloy or tungsten-based alloys) if the application requires.

The configurations shown for the bistable tubular 24 are illustrative of the operation of a basic bistable cell. Other configurations may be suitable, but the concept presented is also valid for these other geometries.

Referring generally to Figures 14 and 15, a side elevational view and a perspective view, respectively, are used to illustrate an expandable tubing 80 made of bi-stable cells 81. As previously described, the bi-stable cells 81 are generally formed of a thin strut 21 and a thick strut 22 which

intersect at either end 84. In the exemplary embodiment shown in the figures, the end 82 of the tubing 80 comprises a plurality of end extensions 86. The end extensions 86 are connected to an end 84 of the cells 81 nearest the tubing end 82 so that the end extensions 86 extend beyond the cells 81 of the tubing. The tubing may have end extensions on one or both ends thereof.

Further, although the figure illustrates an end extension on all of the endmost cells, alternative embodiments may have end extensions 86 on some portion of such cells only. The end extensions 86 are useful for connecting adjacent expandable tubings as further discussed below as well as for other uses. Note that the end extensions do not undergo deformation as the tubing is expanded. The end extensions may be integrally formed or otherwise attached such as by welding or other attachment methods.

Referring generally to Figures 16A-E, a detailed sequence is illustrated of one embodiment of end extensions 86 being connected to adjacent tubings having an associated connector 90. As shown in the figures, one of the end extensions 86 includes an opening 92 formed therein. Although shown as a slot in the

Figures 16A-E, the opening 92 may take other forms such as a hole drilled in the end, collets, or other types of openings 92. The opening 92 of the disclosed embodiment forms a narrow outer portion 94 and a wide inner portion 96. The opening 92 also may have a slot 98 at the back of the opening 92. The end 100 of the end extension 86 has a slanted, or tapered, interior 102 and a slanted, or tapered, exterior 104. Although shown as slanted, the end 100 may be blunt, rounded or some other shape.

10 A pin 110 mounted to the end of a corresponding extension 86 has a broad head 112 with a slanted forward face 114. The pin 110 is shaped and sized to mate with the opening 92. The figures show how the pin 110 passes through the outer portion 94 of the opening 92. As the pin 110 passes through the outer portion 94, the opposing sides flex outwardly (Figure 16B) to accommodate the relatively larger head 112. Once the head is positioned in the inner portion 96 (Figure 16C), the sides may flex back to their original position or near their original position. The slot 98 may provide added resiliency to facilitate placement of the pin 110 in the opening 92.

Once the head 112 is positioned inside the opening 92, sleeve 120 slides over the mating pin 110 and opening 92 to

maintain them in mating connection (see Figures 16D and 16E).

The slanted exterior 104 of the end extension 86 facilitates movement of the sleeve 120 thereon. Note that the sleeve may be replaced by a clip surrounding the mating pin 110 and opening 92 or other device that can maintain the relative position of the mating pieces.

It should also be noted that in one embodiment, the head 112 provides for some plastic deformation of the sides of the end extension 86 so that the sides remain slightly flared. The flared sides provide for increased friction useful in holding the sleeve in place. Alternatively the end extensions 86 may provide detents or other mechanisms to prevent the sleeve from slipping out of position.

Referring to Figures 17A-D, an alternative embodiment for connecting the end extensions 86 of adjacent tubings is illustrated. In this embodiment, both end extensions 86 have openings 92 formed therein. Once the end extensions 86 are positioned adjacent one another, mating connectors 122 are moved into the openings 92 to maintain the relative position of the end extensions 86. As with the prior embodiment, the connector 122 has widened head portions 112 that fit within wide inner

portions 96 of the openings 92. A sleeve 120 slides over the mating connector 122 and openings 92 to help maintain their relative positions. Note that the connectors 122 may have detents or other features that eliminate the need for the sleeve
5 120. Alternatively, the sleeve 120 may be replaced with a clip, adhesive, resin, tape, or other manner of holding the connector 122 in the openings 92. Although the above description relies on the use of end extensions 86 they may be omitted in certain alternative embodiments with the openings formed at the end of
10 the endmost cells.

Also, note that other types of expandable tubings may benefit from the connection type taught herein. For example, as illustrated in Figure 18, an expandable slotted tube 130 of the
15 type disclosed in U.S. Patent No. 5,366,012, issued November 22, 1994 to Lohbeck has overlapping longitudinal slots. As can be viewed in Figure 18, tubing 130 has end extensions 86 with openings 92 formed therein. The end extensions and openings may be used to connect the tubing 130 to an adjacent tubing in a
20 manner similar to that previously described. As with the other embodiments, these types of connectors readily allow expansion of the connected ends of the tubulars along with the rest of the

tubular as opposed to the traditional connection systems that are not as amenable to expansion.

In Figure 19, another alternative embodiment is illustrated in which the connector 122 has sides 142 that slant inwardly approaching one end. The sides 140 of the mating opening 92 also slant inwardly such that the connector 122 may be placed in the opening in one direction only. The tolerance between the opening 92 and the connector 122 holds the connector in place in one direction. The slanted surfaces 140, 142 may be replaced with equivalents such as shoulders and the like. The embodiment shown also has a clip 144 with resilient side arms and detents 146 that mate with indentations 148 formed in the end extensions 86. The detents 146 and indentations 148 mate to hold the clip 144 on the end extension 86. The clip 144 is placed on the side through which the connector 122 is placed.

Illustrated in Figure 20 is another alternative embodiment in which the openings 92 do not open to the ends of the end extensions 86. A connector 150 has side members 152 that are coupled to retention members 154. Retention members 154 are sized to extend through the openings 92 into engagement with side members 152. Side members 152 may be coupled to retention

members by a variety of mechanisms including snap fits,
permanent fixation or fasteners. The tensile strength of the
combined connections should be sufficient to prevent separation
of the connected tubings. Accordingly, the connector may be
5 formed of a material that is different from the material of the
tubing.

Referring generally to Figures 21A-21C, another embodiment
of an expandable connection system is illustrated. In this
10 embodiment, a first tubular 160 is coupled to a second tubular
162 by a connection system 164. First tubular 160 and second
tubular 162 may be comprised of a plurality of bistable cells,
as described above. Additionally, connection system 164 may be
designed to function similarly to the embodiments described
15 above.

As illustrated, connection system 164 comprises a receiving
end 166 extending from first tubular 160 and an insertion end
168 extending from second tubular 162. The exemplary receiving
20 end 166 comprises a plurality of extensions 170 that define a
plurality of openings 172 each having a narrow outer portion 174
and a wider inner portion 176 similar to openings described
above. Insertion end 168 comprises a plurality of pins or broad

heads 178 that may be tapered towards a leading edge for
insertion into openings 172 through the narrow outer portions
174. Each of the pins 178 includes a recessed retention feature
179 designed to engage a corresponding retention feature 180 of
5 each extension 170. Retention features 179 and 180 are designed
to prevent inadvertent separation of first tubular 160 and
second tubular 162. Additionally, a retention member 181, e.g.
an expandable slide cover, is mounted to at least one of first
tubular 160 and second tubular 162. In the embodiment
10 illustrated, retention member 181 is slidably mounted to first
tubular 160 such that it may be moved over extensions 170 and
pins 178 after coupling of first tubular 160 to second tubular
162 to secure the connection. In the example illustrated,
retention features 179 and 180 do not extend radially outward
15 beyond the outside diameter of first tubular 160 and second
tubular 162. Thus, the outside diameter of the collective
extensions of connector system 164 does not exceed the outside
diameters of first and second tubulars 160 and 162.

20 An exemplary retention member 181 is a slide cover
comprising a plurality of separable sections 182 that each have
a pair of longitudinal openings 183 through which a pair of
cooperating extensions 170 are received (see Figures 21D and

21E). When the slide cover is in a disengaged position as illustrated in Figure 21A, cooperating extensions 170 may be sufficiently spread to receive a pin 178 as illustrated in Figure 21B. Once extensions 170 and pins 178 are interlocked, 5 the slide cover is moved to an engaged position, as illustrated in Figure 21C. In this engaged position, extensions 170 are prevented from spreading by virtue of their capture within openings 183. Separable sections 182 may be independent of each other or connected by an expandable material or flexible 10 connection that permits radial expansion of retention member 181.

Additionally, the slide cover may comprise one or more integrated locking devices 184 used to hold the slide cover in 15 its engaged position, although the locking devices also can be used to hold the slide cover in the disengaged position. An exemplary locking device 184 comprises a plurality of threaded studs 185 threadably received through corresponding sections 182. One or more of the threaded studs 185 may be rotated and 20 moved radially inwardly to hold the slide cover or at least the corresponding section 182 at a desired location. For example, when the slide cover is moved to the engaged position, threaded studs 185 are rotated inwardly, as illustrated in Figures 21E

and 22, to prevent the slide cover from being inadvertently moved to the disengaged position. Specifically, extensions 170 are designed to block movement of the studs 185 towards a disengaged position once threaded radially inwardly a sufficient amount.

Additionally, connection system 164 may comprise a sand barrier 186 designed to limit the influx of sand through connection system 164. In this embodiment, sand barrier 186 is disposed along the interior of connection system 164. For example, at least a portion of sand barrier 186 may be coupled to the interior of first tubular 160 such that it extends beyond extensions 170. (See Figure 21A). When first tubular 160 and second tubular 162 are moved together, sand barrier 186 moves into the interior of second tubular 162 as pins 178 are inserted into openings 172, as illustrated best in Figure 21B. Following insertion, slide cover 181 is moved towards second tubular 162 and over the interlocked extensions 170 and 178 to further assist in preventing unwanted separation of the tubular components.

Referring generally to Figure 22, one exemplary embodiment of this internal type of sand barrier is illustrated. In this

embodiment, a sand barrier sand sleeve 188 is connected to the interior of first tubular 160 by, for example, a plurality of pins 190 received in corresponding slots 192 formed in tubular 160. Another exemplary mechanism for fastening sand barrier sleeve 188 to tubular 160 is a plurality of weldments placed on selected portions of the tubular so as to not interfere with expansion. Weldments can be used alone or in addition to other retention features, such as pins 190. A barrier cap 194 is affixed to second tubular 162 by, for example, pins 196 and/or appropriate weldments. Barrier cap 194 comprises a recessed region 198 for receiving and holding sand barrier sleeve 188 when first tubular 160 and second tubular 162 are coupled together. A plurality of barrier sheets 199 may be combined with or incorporated into sand sleeve 188. Exemplary barrier sheets 199 comprise overlapping, metallic sheets that permit expansion of the sand barrier 186 without effecting blockage of sand influx. Other exemplary barriers comprise woven filtration materials, slotted metallic sheets with slots sized according to desired filtration parameters, or elastomeric materials.

An alternate embodiment of the sand barrier is illustrated in Figures 23A-23C and labeled as sand barrier 200. In this embodiment, the illustrated connection system 164 is similar to

that shown and described in Figures 21A-21C. Sand barrier 200, however, is an external sand barrier similar in design to the interior sand barrier 186, except disposed to slide over the exterior of connection system 164.

5

For example, sand barrier 200 may be attached along the exterior of first tubular 160 by appropriate fasteners, weldments, etc., as illustrated best in Figures 23A and 23C. As insertion end 168 of second tubular 162 is moved into engagement
10 with receiving end 166 of first tubular 160, sand barrier 200 moves over second tubular 162 and covers connection system 164, as best illustrated in Figure 23B. One exemplary sand barrier 200 comprises an outer shroud 202 covering one or more barrier sheets 204 (see Figure 23C), however a variety of layers and
15 materials can be combined to create the sand barrier. An exemplary sand barrier is made from a material that is hyperelastic, capable of shape memory, or made from other expandable materials, such as titanium alloys, to achieve the desired expansion effect.

20

Another exemplary embodiment of a sand barrier is illustrated in Figures 24A-24C. In this embodiment, a sand barrier 210 comprises an expandable shroud and filter layer 212

that is pulled over a first run-in guide 214, as illustrated in Figure 24A. The shroud and filter layer 212 is moved over run-in guide 214 (see Figure 24B) until it is positioned generally between run-in guide 214 and a secondary run-in guide 216, as
5 illustrated best in Figure 24C.

Referring generally to Figures 25 and 26, additional embodiments of the present invention are illustrated in the form of crossover devices. For example, in Figure 25, an expandable
10 crossover 220 is illustrated. Expandable crossover 220 comprises an expandable section 222 and a solid section 224. Crossover 220 typically comprises a connector end 226 having, for example, internal threads for threaded engagement with an adjacent component. Also, the expandable section may be formed
15 with one or more bistable cells.

Additionally, expandable crossover 220 comprises a connector 228 generally opposite connector end 226. Connector 228 may be any of a variety of the connectors described above
20 including, for example, a plurality of extension pins designed for receipt in corresponding extensions. Furthermore, any of the variety of sand barriers discussed above can be combined with expandable crossover 220 proximate connector 228.

Expandable section 222 also may comprise or be combined with a variety of other components. For example, sand filtration materials and outer shrouds may be incorporated into the design of expandable section 222. Furthermore, expandable section 222 may be surrounded with an elastomeric material, e.g. rubber jacket, for a variety of applications. These are just a few examples illustrating the adaptability of the crossover device.

10

In another embodiment illustrated in Figure 26, the crossover is a rigid crossover 230. Though the rigid crossover 230 is not expanded, it can be combined with an expandable-style connector 232. With connector 232, expandable sand barriers, such as those discussed above, can be incorporated into the design to limit the influx of sand through connector 232. Opposite connector 232, rigid crossover 230 comprises a connector end 234 that may be tapered and comprise a threaded region 236.

20

Referring generally to Figures 27A-27D, another technique is illustrated for coupling the first tubular 160 with the

second tubular 162. The technique may be utilized with expandable and non-expandable tubulars.

In this embodiment, a connector system 240 is used to couple first tubular 160 with second tubular 162. Connector system 240 comprises a first connector portion 242 coupled to first tubular 160 and a second connector portion 244 coupled to second tubular 162. First and second connector portions 242, 244 may be separate components attached to the corresponding tubulars, or they may be integrally formed with the tubulars.

First connector portion 242 comprises a plurality of extensions 246 separated by gaps 248, as illustrated best in Figure 27A. Similarly, second connector portion 244 comprises a plurality of axial extensions 250 separated by axial gaps 252. Axial gaps 252 are sized to receive extensions 246, and gaps 248 are sized to receive axial extensions 250, as illustrated in Figure 27B.

Furthermore, extensions 246 comprise a first interlock mechanism 254, and axial extensions 250 comprise a second interlock mechanism 256 designed to engage first interlock mechanism 254. Connector system 240 becomes interlocked when

extensions 246, 250 are moved axially into their cooperating gaps 252, 248, respectively, and tubulars 160 and 162 are rotated with respect to each other, as illustrated best in Figure 27C. In the specific embodiment illustrated, first
5 interlock mechanism 254 comprises a plurality of circumferentially oriented ridges 258 separated by spaces 260. The circumferentially oriented ridges 258 extend radially inwardly.

10 Similarly, an exemplary second interlock mechanism 256 comprises a plurality of outwardly extending ridges 262 separated by spaces 264. Outwardly extending ridges 262 are circumferentially oriented for receipt in spaces 260 when first tubular 160 and second tubular 162 are rotated to interlock
15 connector system 240. Similarly, ridges 258 are sized and oriented for receipt in spaces 264 when connector system 240 is interlocked.

To secure the interlocking of extensions 246 with axial
20 extensions 250, one or more sleeves, such as sliding covers 266, may be mounted over selected extensions, as illustrated in Figures 27C and 27D. For example, sliding cover or covers 266 may be slidably disposed on one of the axial extensions 250.

The sliding cover is positioned at a location that does not interfere with the insertion of extensions 246 into axial gaps 252 or the rotation of first interlock mechanism 254 into engagement with second interlock mechanism 256, as illustrated
5 best in Figure 27C.

Once interlocked, each of the one or more sliding covers 266 is slid over the mating first interlock mechanism 254 and second interlock mechanism 256, as illustrated best in Figure
10 27D. The sliding cover 266 is sized to prevent the interlocked ridges 258 and 262 from separating and/or rotating with respect to each other. If desired, each sliding cover 266 may be held at a desired location over first interlock mechanism 254 and second interlock mechanism 256 by, for example, a friction fit,
15 detents, set screws, a weldment or other fastening mechanisms.

In some applications, first tubular 160 and/or second tubular 162 are expanded within the wellbore. The unique design of interlocked extensions with gaps therebetween allows
20 connector system 240 to be expanded along with tubulars 160 and 162.

The particular embodiments disclosed herein are illustrative only, as the invention may be modified and practiced in different but equivalent manners apparent to those skilled in the art having the benefit of the teachings herein.

5 Furthermore, no limitations are intended to the details of construction or design herein shown, other than as described in the claims below. It is therefore evident that the particular embodiments disclosed above may be altered or modified and all such variations are considered within the scope and spirit of
10 the invention. Accordingly, the protection sought herein is as set forth in the claims below.
